Harmonisation Score: Step 2

12 Oct 2026 · What changed, how to read it, and where it sits in the pre-read – without the tool passing judgement.

What is it?

The decision matrix from 0.35.0 gains three connections. None of them changes the arithmetic – they show the finding differently or somewhere else: as the change against an earlier state, as an AI-phrased reading, and as an annex of the conference pre-read.

What it does

• Change between two states: --since DATE recomputes the earlier state from the dated assessments, --delta FOLDER compares against a second workspace; score, confidence, spread, assessments, board decisions, processes – “no changes” is said explicitly
• AI reading (draft): --narrate; the model sees only a contract with every number, never persons; numbers guard, labeling, audit; draft below the table and as .reading.md for editing
• Conference pre-read: config field harmonisation (folder) – the matrix appears as an annex after input 4

Three decisions

A lower score is not a worsening. It is a different finding. The change is ordered by process, not by good and bad – unlike the delta briefing, which shows worsenings first because its metrics have a direction.
The AI recommends nothing either. The prompt forbids any recommendation on what to harmonise or how deep. The reading describes where the picture is uncertain and which decisions are open; the judgement stays with the board.
An annex, not input 5. The conference has four inputs. The matrix is a board view and hangs at the back – calling it the fifth input would invent a ritual that does not exist.

How to use it

```
python -m harmonisation C:\\Lagebild\\harmo --since 2026-09-20
python -m harmonisation C:\\Lagebild\\harmo --since 2026-09-20 --narrate
python -m harmonisation C:\\Lagebild\\harmo --narrate mock
```
