

Report language

Field report 19.09.2026 · One page, two languages — and the interface could do five.

What is it?

Report labels were fixed English, while the conference pre-read's header and its four input headings were German. The interface speaks five languages; the report spoke two — neither necessarily the reader's.

How to use it

```
// do nothing: the report follows the window
```

```
// or pin a language:  
"report": {"language": "fr", ...}
```

```
// or for a single run:  
python -m portfolio portfolio.json \  
    --output report.html --lang fr
```

In the GUI: the **Report language** field. The default '—' means 'follow the interface' and stores nothing; leave it alone and the report comes out in the language you are working in.

What comes with it

- 218 keys across de · en · ro · pt · fr in portfolio/report_texts.py — built like build_reports/terminology.py: one dict, one function, no framework
- Composed sentences as whole templates with placeholders rather than concatenated fragments — otherwise other languages' word order cannot be expressed
- Precedence: --lang beats report.language beats the window language; without any of the three, English
- The date format follows: de/ro 19.09.2026, pt/fr 19/09/2026, en 2026-09-19 — up to 0.31.0 EVERY report carried the German format
- One test per language asserting the output differs from English: a catalogue entry that was never wired up would otherwise go unnoticed

What stays English — and why

The **metric names** remain governed by the SAFE/Global switch; they are established terms. The **axis labels inside the embedded charts** come from build_reports and are a package of their own — a German report carries English axes for now. The **Markdown form of the delta briefing** is the input contract of the AI narration, whose language --llm-lang governs.
