Alarm Register (D4)

14 Oct 2026 · The staff agrees which metric from which value puts which question on the agenda – the tool checks, it invents nothing.

What is it?

A picture full of metrics wakes nobody. An alarm does – when it was agreed beforehand when it rings and what happens then. The decision-point alarm for cross-value-stream pressure (P4) was the first instance; now there is a register for any metric.

What it does

• Per point: metric as a fact path, comparison, threshold, question, agreed reaction, team – whatever can be asked can be alarmed
• Four states, all visible: triggered, below threshold, not agreed, not computable
• Appears in the report, the snapshot and the delta ('newly triggered'); --alarms writes the protocol
• Relative changes (unit %) to the previous stand, register counts per status, the P4 pressure as a path

Three decisions

No threshold, no alarm. A point without an agreed threshold is shown but never alarms – the threshold belongs in the ritual, not in a default.
Below threshold stays visible. An indicator that appears only for bad values teaches its readers to read absence as 'not computed'.
No priority, no recommendation. The order is the state; what follows from a triggered point is the agreed reaction – written by the staff, not the tool.

How to use it

```
solution.json: "decision_points": "registers/decision_points.json"
python -m portfolio solution.json --output report.html
python -m portfolio solution.json --alarms points.md --since-snapshot prev.json
```
