

Flow-Problem Backlog

Feature B6 (VSC-1) · The Value-Stream Conference's most important input — with a conference pre-read.

What is it?

The workshop named it: risks and flow problems get logged, never mitigated — and return next PI. The backlog makes that pattern measurable: every problem counts in how many conferences it has been on the table. Unresolved problems from the third conference on escalate visibly — sorted first, red counter.

How to use it

```
// flow_problems.json per solution, in the config: "flow_problems": "..."  
{  
  "problems": [{  
    "id": "FP-1",  
    "title": "Test-environment provisioning takes weeks",  
    "status": "open", "conferences": 3,  
    "value_streams": ["ART A", "ART B"],  
    "resolution_commitment": "...", "follow_up_pi": "PI 5"}  
]}
```

```
python -m portfolio portfolio.json --conference preread.html
```

What the report shows

- Survivor rule: unresolved and ≥ 3 conferences → on top and red — non-mitigation becomes visible instead of anecdotal
- Cross-VS is derived, never asserted: more than one affected value stream
- Commitment and follow-up PI per problem — promises get a memory
- Conference pre-read: printable bundle of the meeting inputs (data, impediments with ROAM/dependencies, business objectives)

Guardrails

The conference counter is maintained by people — the tool has no history and invents none. Owners are teams, not persons. A portfolio aggregates all solutions' backlogs with a Solution column.
