The Label Follows the Address

11 Oct 2026 · A banner saying “local” while the data goes elsewhere reassures falsely.

What is it?

Since 0.30.0 the Ollama address is configurable – GUI field, --base-url, OLLAMA_HOST. Pointing it at another machine sent briefing and draft off this machine, yet the Art. 50 banner still read “@ local”, and the operator-evidence log did not hold the address at all. The class hung on the provider name, not on where the request went.

What holds now

• The deployment class is decided per call from the address used: loopback (localhost, 127.0.0.0/8, ::1) stays local, any other address reads remote
• external_api stays what it was: a provider with a contract and a key (Claude)
• The operator-evidence log keeps the address as a SHA-256 hash (endpoint_sha256) – checkable, not readable
• The GUI says it before the call: “The address points to another machine – briefing and draft leave this machine.” In all five languages

Three decisions

Only two classes for Ollama, no third one for “own network”. Whether 10.0.0.5 is a box in the basement or a VPN endpoint in someone else's cloud, the tool cannot know. So it claims only what it knows: the data leaves this machine. And it resolves no names – the class follows from the configuration alone.
The name is remote. It says in the banner exactly what can be shown. self_hosted would have claimed operation by the user, which nobody can verify.
The address goes into the log as a hash. The operator can verify any claimed address; the file reveals no infrastructure – the same rule as for input and output.

How to see it

```
python -m llm test --base-url http://gpu-box:11434
# banner: mistral-nemo @ remote, Prompt v1
# log: "deployment_class": "remote", "endpoint_sha256": "..."
```
